Extended Abstract

# Biomass Direct Liquefaction - Can This Process Become Fully Sustainable and Environmentally Friendly Mateus MM

### Abstract

This short opinion manuscript aims to show a point of view of someone, who believes in bio refineries as an essential tool for a better future. However there are still many unsolved issues, in particular, the lack of alternatives to organic solvents often needed .Although, the bio refineries will be a tool that we can develop and leave as an inheritance for future generations.

### Keywords:

Sustainable; Bio refineries; Wastes; Solvents; Biomass

### Short Communication

At a time when environmental concerns are on the agenda, that the control over the carbon dioxide emissions are more constant and its limits tighter along with new policies being outlined for the upcoming years, it becomes especially pertinent to find other sources of raw materials as an alternative to fossil sources. These latter sources are expected to become scarce and expensive not only because of the market value of crude barrels but also because of its impact on the environment.

The bio-refinery concept is not a new concept at all or even can be considered as one of those "outside of the box", but the truth is that such concept has not been explored as much as it was expected .The high initial investment that, usually, has to be done and the truth is that companies do not always possess the financial structure to deal with such investments, may be one of the main reasons to explain this point.

However thinking in the long term and given that much of the raw material which can be used in biorefineries is sometimes feedstock no value at all or even in some cases the companies receive financial compensation for their elimination, the implementation of bio refineries could become attractive. The bio refineries projects should take into account the nature of the wastes locally available as

Mateus MM Universidade Atlantica,Oeiras, Portugal. <u>rmglopes@ist.utl.pt</u> well as their seasonality which means that those projects must contemplate the versatility of the installation to be built.

Concerning the direct liquefaction of wastes in acid medium, it is usual to consider this procedure a sustainable process, which in principle is not entirely wrong. However, in all truth, there is still an obstacle to be overcome, so we can, in fact, consider direct liquefaction as a fully sustainable process. The reader at this time may become a little bit bewildered with this last statement. However, we must be aware of one point, which may be regarded as a drawback of this procedure. The use of organic solvents, including the use of polyhydric alcohols, which are often, produced products that result from fossil sources, are still a barrier that must be torn down, so the process becomes fully sustainable. We have beheld some remarkable and frankly positive advances over the last years with the exploitation of natural and renewable sources. Regarding the lignocellulose residues, many compounds can be accessed from these sources .From fuels and value-added chemicals to substrates for the production of bio products through fermentation or even antioxidant additives, among many others, this process can become a new source of income for companies that are generating these wastes and decide to take the step needed and invest in bio refineries to valorize the wastes created from their production line.

If we consider the life cycles of raw materials and products obtained from the direct liquefaction we may outline, not a simple, closed and carbon dioxide neutral cycle, but a complex web of interconnected cycles which altogether can form a neutral carbon dioxide emission system, as well .Although to make all the involved processes of those cycles fully sustainable, petroleum-free formulations' components are extremely needed. The use of solvents from natural sources or industrial wastes as well could and should be considered .The downstream solvents employed in chemical industries, such as pharmaceuticals, fine chemicals could also be a solution. That will allow not only the elimination of very expensive treatments that usual are needed to eliminate such residues and at the same time making feasible at acceptable costs the
