Double eyelid procedure: Orbicularis-levator fixation technique**Adolfo Napolez**

Southern Illinois University, USA

Asian eyelids have several characteristics that distinguish them from the eyelids of people from European and African descent. These include: 1) low, poorly defined or absent lid creases, 2) pronounced fullness to the upper and lower lids, 3) narrow palpebral fissures and 4) epicanthal folds. The extent to which these anatomic variants are present, determines the height and prominence or absence altogether of the upper lid crease in the Asian eyelid. Asian blepharoplasty is the most common Cosmetic Surgery procedure done in the Far East, with many variants noted. The discussion will include the patient selection, preparation, anesthesia, and surgical technique utilized in the operation for the creation of the double eyelid in the patient.
