Identifying electrochemical limitations of solar energy storage

Luca Bertoluzzi
Stanford University, USA

Solar energy storage is achieved through the conversion of solar energy into a chemical fuel. This conversion is performed via at least one semiconductor material. One popular example is water splitting, which consists in splitting water into its primary components, hydrogen (which can be stored and used as a fuel) and oxygen. Water splitting occurs at the interface between the semiconductor and water via photo-activated electrochemical reactions. An efficient light to chemical fuel conversion relies on the use of semiconductors with the appropriate optical properties, energetics, robustness and cost. To fulfill these criteria, cheap semiconductor oxides such as $\text{Fe}_2\text{O}_3$, $\text{TiO}_2$, $\text{BiVO}_4$ and $\text{WO}_3$ have been investigated in the past decade. The low temperature processing and deposition techniques of these materials induce the presence of a large density of defects. These states strongly affect the kinetic of the electrochemical reactions which generate the solar fuel. While several solutions may be applied to tackle this type of limitation (coating layers, catalyst layers, surface defect passivation), it is primordial to identify, beforehand, the role of these defects on solar energy storage. In this talk, the modeling of the various possible impacts of defect states on solar fuel production will be discussed in a first part. In the second part, it will be shown how frequency and time dependent electrochemical techniques such as impedance spectroscopy, light intensity modulated spectroscopy and photocurrent decays allow identifying these states. It will also be explained how to quantify their impact on the semiconductor energetics and the kinetics of the electrochemical reactions which generate the solar fuel. Finally, a general methodology will be proposed to choose the most appropriate technique for the optimization of this technology.

Biography

Luca Bertoluzzi is currently a Postdoctoral Fellow at Stanford University, USA. After obtaining his PhD in Physics from Jaume I University, Spain, he won an Early Postdoc Mobility Fellowship from the Swiss National Science Foundation. He is specialized in the modeling of photoelectrochemical processes in solar cells (dye sensitized solar cells and perovskite solar cells) and photoelectrodes used for solar fuel production. His recent works are based on the analysis and modeling of the impact of defect states on solar energy production and storage with impedance spectroscopy, light intensity modulated spectroscopy and transient photovoltage and photocurrent techniques.
