Aim: Ghrelin is a 28-amino acid that is produced in the stomach. Strong evidence indicates the effects of ghrelin in its potential role in the pathogenesis of obesity, insulin resistance (IR) and type 2 diabetes. The aim of this study was to investigate the relationship of ghrelin levels with obesity, insulin resistance and glucose in normal and obese subjects.

Methods: Twenty subjects (normal weight=13) and (Obese=7) aged 20-22 out of 250 students participated in the study. Fasting plasma ghrelin, insulin and glucose levels were measured after overnight fasting. Insulin resistance was also calculated by HOMA-IR. The study received approval from the ethical committees of “Zayed University” and “Doctors Medical Center” while all subjects signed a consent form. Body weight and height was collected for all subjects using SECA 600 model while obesity was defined as BMI>30 kg/m2, according to the criteria of international obesity task force plasma ghrelin, glucose, insulin and C-reactive protein (CRP) levels were measured in the morning after fasting overnight.

Conclusions: Ghrelin levels are significantly lower in obese subjects. Moreover, Obesity (BMI) and Insulin resistance (HOMA)-IR are significantly independently associated with ghrelin levels in obese college students. More studies are needed to elucidate the relationship of ghrelin with BMI and IR.
