Rhabdomyosarcoma (RMS) is the soft tissue tumor derived from (formed from) embryonic primary mesenchyme. Neck, head and genitourinary region are the common locations that are affected by this disease. This study reports a 16 years old girl presented with vaginal bleeding and irregular menstruation. Biopsy results showed rhabdomyosarcoma. 2 Ultrasounds and MRI were performed and revealed two solid mass in size of 50 x 80 in the lower uterine cervix. Then base on diagnosis of 15 course chemotherapies and abdominopelvic CT scan it is illustrated that the mass puts pressure on the rectum and bladder. Therefore considering lack of adequate clinical response she underwent a total hysterectomy.

Biography

Mohammad Reza Hashempour has completed his Doctorate at the age of 25 years from Army University of Medical Sciences and postdoctoral studies in Surgery from Golestan University School of Medicine. He has published papers in reputed journals.
