ABSTRACT

Aim: To study the status of ear, nose and throat in the patients diagnosed with the COVID-19.

Materials and methods: This is a perspective study in patients admitted in the isolation wards of Dr. Sushila Tiwari Hospital Haldwani between March 2020 and July 2020. There were 465 symptomatic patients out of total 727 patients diagnosed with COVID19.

Results: Since the COVID-19 pandemic has begun, many individuals have noted many ENT manifestations along with the other general symptoms like fever (395 pt) > cough (326 pt) > weakness/fatigue (190 pt) > difficulty in breathing (89 pt) > muscle ache (58 pt) > headache (56 pt) and diarrhea (24 pt). Among ENT manifestations throat symptoms were found most common including loss of taste in 74 pt. It was noticed that most commonly sweet and salt goes first then sour taste vanish and bitter and chilly taste goes in the end, most of them were reversible after 2-3 weeks. Among nasal symptoms nasal congestion was found most common (72 pt) followed by loss of smell (88 pt), nasal blockage (66 pt) and runny nose (47 pt). Loss of smell was also reversible in most of the cases after 2-3 weeks. Ear symptoms were not so commonly found. Although itching in bilateral ear, sensation of ear fullness, ear ache and conductive hearing loss were complained by some patients.

Conclusion: This study represents the initial findings of all individuals with ENT manifestations along with the chemosensory loss in the symptomatic confirmed COVID-19 patients. During the ongoing COVID-19 pandemic, changes in smell or taste are not being considered indicative of possible COVID-19 infection especially in the absence of other high-suspicion symptoms.

Keywords: COVID-19; Loss of taste; Loss of smell; ENT manifestations; Ear symptoms

INTRODUCTION

Coronaviruses are a group of related RNA viruses that cause diseases in mammals and birds. In humans, these viruses cause respiratory tract infections that can range from mild to lethal. Mild illnesses include some cases of the common cold (which is also caused by other viruses, predominantly rhinoviruses), while more lethal varieties can cause SARS, MERS, and COVID-19 [1-6]. They are enveloped viruses with a positive-sense single-stranded RNA genome and a nucleocapsid of helical symmetry [7]. The genome size of coronaviruses ranges from approximately 26 to 32 kilo bases, one of the largest among RNA viruses [8].

They have characteristic club-shaped spikes that project from their surface, which in electron micrographs create an image reminiscent of the solar corona, from which their name derives [9]. The coronavirus surface spikes are homotrimers of the S protein, which is composed of an S1 and S2 subunit. The homotrimeric S protein is a class I fusion protein which mediates the receptor binding and membrane fusion between the virus and host cell. The S1 subunit forms the head of the spike and has the Receptor Binding Domain (RBD). The S2 subunit forms the stem which anchors the spike in the viral envelope and on protease activation enables fusion. The E and M protein are important in forming the viral envelope and

maintaining its structural shape. Transmission Infected carriers are able to shed viruses into the environment. The interaction of the coronavirus spike protein with its complementary cell receptor is central in determining the tissue tropism, infectivity, and species range of the released virus. Coronaviruses mainly target epithelial cells [5]. They are transmitted from one host to another host, depending on the coronavirus species, by either an aerosol, fomite, or fecal-oral route. The incubation time for COVID-19 since the exposure to SARS-CoV-2 is believed to reach 14 days, nevertheless, the majority of patients develop COVID-19 disease after 4-5 days (range between 2 and 7 days) after being infected [4,5]. COVID-19 remains contagious even during the latency period, thus patients before clinical COVID-19 presentation can transfer the virus to others.

MATERIALS AND METHODS

Infection in humans

In December 2019, a pneumonia outbreak was reported in Wuhan, China. On 31 December 2019, the outbreak was traced to a novel strain of coronavirus, which was given the interim name 2019-nCoV by the World Health Organization (WHO), later renamed SARSCoV-2 by the International Committee on Taxonomy of Viruses. As of 31 July 2020, there have been at least 675,545 confirmed deaths and more than 17,406,644 confirmed cases in the COVID-19 pandemic worldwide and at least 35,745 deaths and more than 1,638,827 confirmed cases of COVID-19 in India.

Aim

The aim of study is to see ENT manifestations in corona affected patients admitted in the isolation wards of Dr. Sushila Tiwari Hospital haldwani since 1/4/2020 till 31/7/2020.

Sampling technique: Total enumeration.

Prévalence of symptomatic patients admitted in STH: 0.64 (64%)

Inclusion criteria

All symptomatic COVID-19 affected patients admitted in isolation wards oSTH haldwani.

Exclusion criteria

Patients or guardian refusal for consent.

RESULTS

From 01/04/2020 till 31/07/2020, a total of 465 respondents met inclusion. Which were COVID-19 positive symptomatic patients by testing or diagnosis by a health care practitioner in STH Haldwani? Although most respondents experienced other major COVID-19-related symptoms during or after their chemosensory change in Table 1.

Table 1: Coexisting symptoms associated with chemosensory changes.

Symptoms	Respondents, No.(%)
Symptomatic COVID-19 patients	
CDC major symptoms	
Difficulty breathing	89(19.2)
Cough	326(70.2%)
Fever	395(85%)
Muscle aches	58(12.5%)
Headaches	56(12%)
Other symptoms	
Weakness or fatigue	190(41%)
Diarrhea	24(5.2%)

Among ENT manifestations throat symptoms were found most common including loss of taste in 74 pt. It was noticed that most commonly sweet and salt goes first then sour taste vanish and bitter and chilli taste goes in the end, most of them were reversible after 2-3 weeks. Among nasal symptoms nasal congestion was found most common (72 pt) followed by loss of smell (88 pt), nasal blockage (66 pt) and runny nose (47 pt). Loss of smell was also reversible in most of the cases after 2-3 weeks.

Ear symptoms were not so commonly found. Although itching in bilateral ear, sensation of ear fullness, ear ache and conductive hearing loss were complained by some patients.

DISCUSSION

To date, preliminary work has demonstrated a high incidence of otorhinolaryngological changes along with smell or taste change in patients with COVID-19. However, the wide variation in populations studied methods of recruitment, Figure 1 coexisting symptoms at the time of ENT manifestations. Figure 2 shows patients presented with various nasal symptoms. Figure 3 Subjective smell prior to and while symptomatic (all patients) presented with partial (50) and complete (38) loss of smell which is completely reversible in most patients.

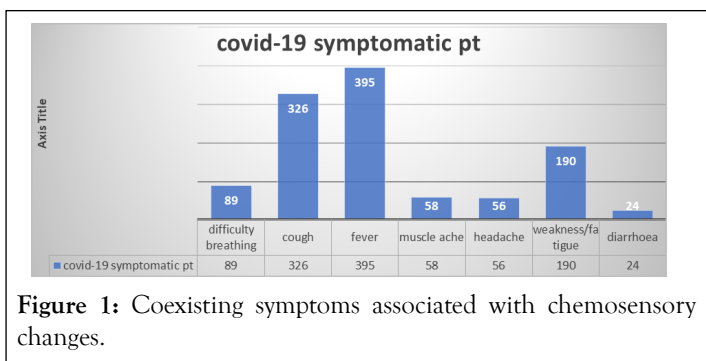

Figure 1: Coexisting symptoms associated with chemosensory changes.

Figure 2: Patients presented with nasal symptoms.

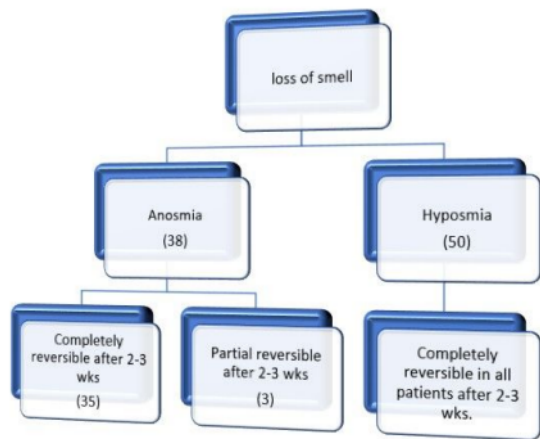

Figure 3: Shows grading and reversibility found in respondents.

Figure 4 shows ear manifestations prior to and while symptomatic (all patients). Figure 5 shows throat symptoms prior to and while symptomatic (all patients). Figure 6 shows the pattern of loss of taste sensations which was completely reversible in most of the cases.

Figure 4: Patients presented with Ear manifestations.

Figure 5: Patients presented with throat symptoms.

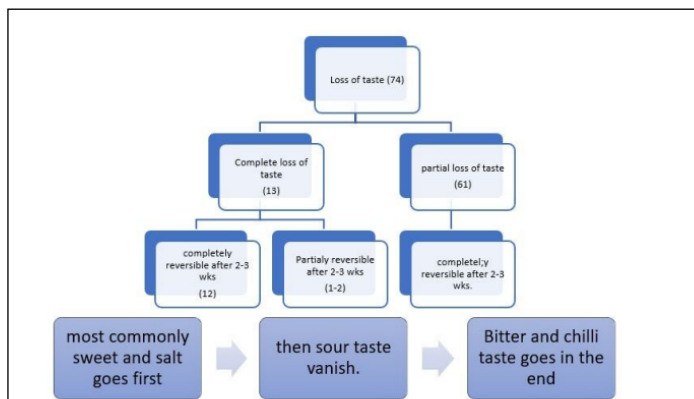

Figure 6: Shows a brief description about grading, reversibility and type of loss of taste found.

Irrespective, chemosensory changes associated with COVID-19 are well established, leading most health organizations worldwide to include acute changes in smell or taste among symptoms suggestive of COVID-19. Despite this, many patients with new-onset chemosensory deficits are still not suspected of COVID-19 infection or tested as such. Reasons for lack of testing are likely several and may owe largely to limited availability as well as a lack of understanding in the lay and medical communities of the association between smell/taste and COVID-19. Among all respondents experiencing olfactory disturbances in our study, 11.7% cited chemosensory disturbances as their first or only symptom of disease. This is consistent with 11.7% of hospitalized patients with COVID-19 reporting smell or taste disturbances as the initial presenting symptom but substantially higher than other reports based on patient populations with presumably milder disease. The co-occurrence of multiple well known symptoms of COVID-19 suggests that many of these respondents were undiagnosed COVID-19 infections. Some confirmed COVID-19 Patients also presented with subjective discomfort in the bilateral ears and bilateral mild conductive hearing loss [10-16].

CONCLUSION

This study represents the initial findings of a longitudinal survey of all individuals with ENT manifestations along with the chemosensory loss in the symptomatic confirmed COVID-19 patients admitted in the isolation wards of Dr. Sushila Tiwari hospital Haldwani during the COVID-19 pandemic. Patients may present with smell or taste loss before other symptoms and experience complete subjective loss of smell or taste. During the ongoing COVID-19 pandemic, changes in smell or taste are not being considered indicative of possible COVID-19 infection—especially in the absence of other high-suspicion symptoms.

FUNDING

This research received no specific grant from any funding agency.

CONFLICT OF INTEREST

The author hereby declares that there is no potential conflict of interest with respect to research and publication of this article.

ETHICAL STANDARDS

As it is a study involving human participants, ethical clearance was obtained from the institution.

INFORMED CONSENT

Informed consent was obtained for all participants included in the study.
