Abstract

This is a case of a young boy whose name is Arun Mehatha, a resident of Mumbai, India. He is just 19 years old and suffering from a disease of hematopoietic cells which is called as Hematopathology or hemopathology. He has this disease in peripheral blood, bone marrow, lymph node, spleen, and other tissues involved by blood.

Keywords: Hematopoietic cells; Hematopathology; Bone marrow; Peripheral blood; Spleen; Blood tissues

Case Report

The Cedars-Sinai Hematopathology Fellowship offers comprehensive training in diagnostic hematopathology, including bone marrows, peripheral smears, lymphomas, coagulation, special testing, cytogenetics and molecular hematopathology (Figure 1 & 2).

Figure 1: Cedars-sinai hematopathology

Figure 2: Hematopoietic cells

Hematopathology is convoluted in the study of the cellular elements of blood, bone marrow, body fluids, and lymphoid tissues with a focus on neoplastic and non-neoplastic hematologic disorders. In addition to excessive-extent computerized haematology laboratory assessments (e.g. CBCs) (Figure 3).

Figure 3: Acute lymphoblastic leukemia pathology

Acute lymphoblastic leukemia (ALL) is a spiteful (clonal) ailment of the bone marrow in which early lymphoid precursors proliferate and substitute the standard hematopoietic cells of the marrow. ALL is the utmost shared type of cancer and leukemia in progenies in the United States (Figures 4-7) [1].

Figure 4: Neoplastic hematopathology
platelets. Voluminous of the white blood cells may be myeloblasts (often just called blasts), which are undeveloped blood-forming cells that are not ordinarily found in the blood (Figure 8) [2].

Cord blood stem cells

Umbilical cord blood comprises predominantly red blood cells, white blood cells, platelets, plasma and there are limited hematopoietic stem cells in this blend (in Bertrand’s case, a meager 160 million). When a child’s cord blood is “banked”, the dispensation center does its preeminent to harvest (Figure 9).

Atypical lymphocytes vs. monocytes

The CSF smear presented on the right was taken from a patient with partly canned bacterial meningitis. Neutrophils are the predominant cell type; on the other hand, there are also monocytes and a small number of typical lymphocytes. Atypical lymphocytes are exposed here. These WBC’s are ‘atypical’ for the reason that they are larger (more cytoplasm) and obligate nucleoli in their nuclei. The cytoplasm has a tendency to be indented by adjoining RBC’s. Such unusual lymphocytes are over and over again accompanying with infectious mononucleosis from Epstein-Barr virus (EBV) infection (Figure 10).

Murine polymorphonuclear neutrophils (PMN) were scrutinized for fungicidal and fungistatic activity counter to yeast cells of *Histoplasma capsulatum*. In a 16-h Limiting Dilution Assay (LDA) (persistent sum of PMN contrasted with dwindling amounts of yeast cells) where PMN to yeast cell ratios were high (0.4-1.5 × 10(5):1). This is a photo of the dimorphic fungus *Histoplasma capsulatum*, the causative agent of Histoplasmosis, inside neutrophils in a peripheral blood smear. In the wild, *H. capsulatum* grows as a mycelial fungus, producing microconidia that can be inhaled (Figure 11) [3].
B-cell lymphomas are much more common than T-cell lymphomas and account for approximately 85 percent of all NHLs. Diffuse Large B-cell Lymphoma (DLBCL or DLBL) is the most common form of NHL, accounting for about 30 percent of newly diagnosed cases of NHL in the United States [4]. Diffuse Large B-cell Lymphoma (DLBCL or DLBL) is a cancer of B cells, a type of white blood cell responsible for producing antibodies. It is the most common type of non-Hodgkin lymphoma among adults, with an annual incidence of 7–8 cases per 100,000 people per year in the USA and the UK.

Chronic lymphocytic leukaemia bone marrow

Chronic Lymphocytic Leukaemia (CLL) represents 80% of cases of leukaemia; peak incidence of 4 years of age; causes dimeralization of bones, periostitis, and lytic lesions; positive TdT nuclear staining. Bone marrow examination refers to the pathologic analysis of samples of bone marrow obtained by bone marrow biopsy (often called a trephine biopsy) and bone marrow aspiration. Bone marrow examination is used in the diagnosis of a number of conditions, including leukaemia, multiple myeloma and anemia. Leukaemia’s typically fill up the marrow with abnormal cells, displacing normal hematopoiesis. The marrow here is essentially 100% cellular, but composed almost exclusively of leukemic cells. Normal hematopoiesis is reduced via replacement (a "myelophtihisic" process) or by suppressed stem cell division.

Conclusion

Already an indispensable a part of habitual hematopathology practice in many instances, the role of molecular diagnostic strategies can handiest be anticipated to develop. Ongoing studies are persevering with to outline molecular cytogenetic abnormalities of diagnostic and prognostic significance in lymphoid and myeloid problems, and there’s growing interest inside the potential medical importance of factor mutations, especially in the myeloid problems, analogous to the JAK2 mutations in polycythemia vera and other myeloproliferative neoplasms. Ongoing expression microarray studies will probably retain to further outline molecularly based totally sub-types of myeloid and lymphoid issues, which can be examined for by using micro-array, multiplex RT-PCR, or some other platform that could provide diagnostic or prognostic facts in routine scientific practice. Gene expression profiling research, at least for the foreseeable destiny, may additionally augment, but are not going to replace conventional morphologic and phenotypic studies in hematopathology.

It consequently stays crucial that pathologists comparing peripheral blood, bone marrow, and lymphoid tissue samples remain acquainted with the spectrum of available molecular diagnostic techniques and be able to integrate their outcomes with the findings of other ancillary studies [5].
