Abstract

Alizarin yellow GG (AYGG) is a natural dye used as a corrosion inhibitor. The inhibitive action of this compound against corrosion of carbon steel in hydrochloric acid solution (1M concentration), has been tested using the weight loss measurements and electrochemical measurements techniques. The results indicates this compound is a good inhibitor for carbon steel in hydrochloric acid solution, and the inhibition efficiency increased as the concentration of this compound increased. Also the results revealed as the temperature increased, efficiency and corrosion activation energies are increased. On the basis of the experimentally determined activation energy values, the addition of this compound can be considered chemisorption adsorbed.

Keywords: Metals; Electrochemical techniques; Chemisorptions; Corrosion

Introduction

Due to increasing industrial applications of steel in acidic solution, study of corrosion phenomena of this metal in acidic solution is so important [1]. The main problem of using carbon steel is its dissolution in acidic solutions [2]. Hydrochloric acid is often used as a pickling acid for iron and its alloys in order to remove corroded metal or any scale formed on surface of the metal. After removal of undesirable rust or scale, the acid used, now is free for further attack on the metal surface. In order to prevent or retard metal dissolution and also reduce acid consumption, corrosion inhibitors are frequently used [3].

Corrosion can be controlled by suitable modification of the environment which in turn stifle, retard or completely stop the anodic or cathodic reactions or both. This is achieved by the use of proper inhibitors. Inhibitors which prevent corrosion are substances which when added to solution in small concentration can decrease or prevent the reaction of the metal with the solution [4].

These compounds can slow down the rate of corrosion processes by:

- Increasing the anodic or cathodic polarization behavior (Tafel slopes)
- Reducing the movement or diffusion of ions to the metallic surface
- Increasing the electrical resistance of the metallic surface

Anodic inhibitors cause a large anodic shift of the corrosion potential, forcing the metallic surface into the passivation range. Cathodic inhibitors either slow down the cathodic reaction, or selectively precipitate on cathodic areas to increase the surface impedance and limit the diffusion of reducible species to these areas. Cathodic inhibitors can provide inhibition by three different mechanisms:

1. As cathodic poisons,
2. As cathodic precipitates, and
3. As oxygen scavenger. Both anodic and cathodic effects are sometimes observed in the presence of organic inhibitors, but as a general rule, organic inhibitors affect the entire surface of a corroding metal when present in sufficient concentration. Organic inhibitors usually designated as film-forming, which protects the metal by forming a hydrophobic film on the metal surface [5].

Organic inhibitors are applied extensively to protect metals from corrosion in many aggressive acidic solution (e.g. in the acid pickling and cleaning processes of metals). Most of these organic inhibitors are nitrogen, sulfur or oxygen containing compounds. The first stage in the action mechanism of these organic inhibitors in aggressive acid solution is their adsorption on the metal surface. The effectiveness of the functional atom in the adsorption processes varies according to the following sequence: S > N > O [6].

Most of commercially pickling inhibitors available are toxic compounds, for this reasons many investigators have tried to replace these compounds with new environmentally friendly inhibitors [7]. Due to this fact several different compounds have been investigated as natural corrosion inhibitors; such as, natural honey, berberine, caffeic acid, and etc [8-11].

Alizarin yellow GG (AYGG) C13H8N3NaO6 (an azo dye) [3-(3-nitrophenoxyazo)-2–hydroxybenzoic acid sodium salt] is a natural dye and it is considered to be an environmentally friendly compound, used in H2SO4 Solution [12].

In the present paper, by employing this compound (AYGG), the corrosion behavior of carbon steel in 1M HCl, has been studied, using the weight loss, polarization measurements and electrochemical impedance spectroscopy methods. The molecular structure of AYGG used in this study is shown in Figure 1.

Polarization measurements

Electrochemical measurements were carried out in a conventional three electrode cylindrical glass cell, containing 800 ml of electrolyte at the room temperature (25 ± 1°C). A saturated calomel electrode (SCE) and platinum electrode are used as reference and auxiliary electrode, respectively. Polarization studies were conducted using computer controlled ZAHNER Elektrik model IM6eX potentiostat at a scan rate of 0.5 mV/s. THALES software was used for evaluating the experimental data. Before recording the polarization curves, the solution was de-aerated for 20 min and the working electrode was maintained at its corrosion potential for 25 minutes until a steady state was obtained.

The inhibition efficiency (IE %) was calculated using the following equation:

\[ \text{IE}_% = \frac{I_1 - I_2}{I_1} \times 100 \]  

Where, \( I_1 \) and \( I_2 \) are the corrosion current densities of carbon steel in the absence and presence of inhibitor, respectively.

Electrochemical impedance spectroscopy (EIS)

EIS experiments were conducted using computer controlled ZAHNER Elektrik model IM6eX system with THALES software. Data from Zview software were used for calculation of polarization resistance (\( R_p \)) and double layer capacitance (\( C_{dl} \)).

All experiments were performed with a frequency ranging from 100 mHz to 10 kHz and peak-to-peak ac amplitude of 10 mV. The impedance diagrams were plotted in the Nyquist presentation form.

The inhibition efficiency (IE %) was calculated using the following equation:

\[ \text{IE}_% = \frac{R_p - R_{p_i}}{R_p} \times 100 \]  

Where, \( R_p \) and \( R_{p_i} \) are polarization resistance of carbon steel in the absence and presence of inhibitor, respectively.
Results and Discussion

Weight loss measurements

The results obtained for evaluation of corrosion rate and inhibition efficiency for carbon steel in 1 M HCl solution at 25, 40 and 60°C in the absence and presence of AYGG are given in Table 1. The inhibition efficiency of AYGG as corrosion inhibitor for carbon steel, increased (up to 96.1%), with increasing concentration of this compound (tested at 25 ± 1°C). Also as one can notice, at temperature of 40 and 60°C, maximum inhibition efficiencies achieved for solution containing 0.3 g AYGG per liter of acid solution. The increase in corrosion rate is more pronounced with the rise of temperature for the uninhibited acid solution. As it is expected addition of the inhibitor used, leads to decrease of the corrosion rate. As it is mentioned above, the inhibition efficiency increases with both increase in AYGG concentration and temperature. This support the hypothesis, that the AYGG adsorption is more a chemisorption than a physisorption [13].

Polarization measurements

The result obtained from potentiodynamic polarization parameters of carbon steel immersed in different concentrations of AYGG, are given in Table 2 and the corresponding polarization curves are shown in Figure 2.

From results obtained in Table 2 the addition of AYGG decreases corrosion current density. Also, it can be clearly seen that the inhibition efficiency of AYGG increases with inhibitor corrosion concentration. This behavior is similar to weight loss results, which indicates that AYGG acts as a good corrosion inhibitor for carbon steel in HCl solution.

According to polarization curves, the cathodic slopes Figure 2 decreased with increasing in the AYGG concentration, whereas, anodic slopes changes is in irregular manner. Moreover, in the presence of AYGG the values of corrosion potential $E_{corr}$ vary from -462.3 to -342.7 (mV). Therefore, AYGG could be classified as a cathodic-type inhibitor [1]. The present results indicate a pervasiveness of the inhibitive effect, which implies that the Fe-dye complexes formed an insoluble surface layer which isolated the metal surface from the acidic solution. The integrity of this protective film has been shown to be quite sensitive to the AYGG concentration [14]. The curvature of the anodic branch may be attributed to the deposition of the corroded metal or impurities in the carbon steel (e.g., Fe3C) which forms a non-passive surface film. In addition, inflection in the anodic branches is quite clear, which may be due to passivation of pitting [15].

Electrochemical impedance spectroscopy (EIS)

Figure 3 displays the Nyquist plots of specimens immersed for 30 minutes in HCl solution with different concentrations of AYGG at room temperature (25 ± 1°C). After analyzing the shape of the Nyquist plots, and considering the relevant spectra, the equivalent circuit shown in Figure 4 can be modeled. Where $R_s$ represents solution resistance, $R_p$ polarization resistance and $C_{dl}$ double layer capacitance. As it is noticed the diameter of Nyquist plots ($R_p$) increases with increasing the AYGG concentration. From these results one may conclude that the AYGG acts as a corrosion inhibitor for carbon steel, in 1 M HCl solution. This suggested that, the formed inhibitive film was strengthened by addition of this corrosion inhibitor [16]. The obtained impedance diagrams have almost a semicircular appearance, indicating a charge transfer process which mainly controls the corrosion of carbon steel [17]. It is clear that the shapes of the impedance plots for inhibited electrodes are not

In order to calculate the energy of adsorption ($\Delta G_{ads}$), following equation is used.

$$ K = \frac{1}{55.5} e^{\left(\frac{\Delta G_{ads}}{RT}\right)} $$

(5)

Where the value of 55.5 is the volume ratio of water content in solution in ml/l [18]. Figure 7 clearly shows the dependence of $\Delta G_{ads}$ on T, indicating a well correlation among thermodynamic parameters.

$$ \Delta G_{ads} = \Delta H_{ads} - T\Delta S_{ads} $$

(6)

The free energy of adsorption ($\Delta G_{ads}$) values were calculated and given in Table 4. The negative values of $\Delta G_{ads}$ indicate the stability of the adsorbed layer on the steel surface and spontaneity of the adsorption process.

The dependence of $\Delta G_{ads}$ on temperature can be explained by the following points [1];

(a) $\Delta G_{ads}$ may increase (becomes less negative) with the increase of temperature which indicates the occurrence of exothermic process.

(b) $\Delta G_{ads}$ may decrease (becomes more negative) with increasing temperature indicating the occurrence of endothermic process.

Therefore, the decrease of $\Delta G_{ads}$ with temperature reveals endothermic process of the corrosion inhibition of carbon steel by AYGG compound. In an endothermic process, with increasing temperature inhibitor adsorption will improve [23]. Also the positive sign of enthalpy of adsorption ($\Delta H_{ads}$) indicates that the adsorption of inhibitor molecules is an endothermic process. The entropy of adsorption ($\Delta S_{ads}$) in the presence of AYGG compound is positive, meaning that an increase in disordering takes places going from reactants to the metal adsorbed species reaction complex [24].

process had been distinguished [26], physisorption in which the 1 M HCl solution between 25 and 40 °C, was found to be 47.9 kJ mol⁻¹, temperatures T₁ and T₂, respectively [25].

Values of kinetic and thermodynamic parameters (Eₐ, ΔGₐds), also the activation energy is greater than 40 kJ mol⁻¹. On the basis of the experimentally determined activation energy values, the addition of AYGG compound in HCl solution.

From thermodynamics point of view two types of adsorption process had been distinguished [26], physisorption in which the activation energy is less than 40 kJ mol⁻¹ and chemisorption, where activation energy is greater than 40 kJ mol⁻¹. On the basis of the experimentally determined activation energy values, the addition of this compound can be considered chemisorption adsorbed, and therefore, as the temperature raised, the adsorption of this compound on the surface of metal is improved [26,27].

Conclusions

• From the results obtained, one can conclude that AYGG is an effective corrosion inhibitor for carbon steel in HCl acid solution.
• Inhibition efficiency increased with both increase in temperature and concentration of AYGG compound.
• According to the K values, it is concluded that, the interaction between the inhibitor molecules and the metal surface is improved.

Phenomenon of chemisorption is proposed from the obtained values of kinetic and thermodynamic parameters (Eₐ, ΔGₐds), also the adsorption heat are negative values.
