Abstract

Examination of some Teleost fishes captured in the Maga detention lake located in the Far North Region of Cameroon, revealed the presence of three new species of Myxosporidia of the genera *Myxidium* Bütschli, 1882 and *Myxobolus* Bütschli, 1882 of which complete description is given in the present study. These species are: *Myxidium tetraodoni* sp. nov., parasite of the urinary bladder of *Tetraodon lineatus* Linnaeus, 1758 (Tetraodontidae) that form ellipsoidal spores with a turgid middle part and rounded ends. They measured 11.6 (10.5-12.5) µm long × 8.2 (7.2-9.6) µm broad; the spherical polar capsules are of equal size and measure 3.7 (3.0-4.3) µm. *Myxidium anisocapsularis* sp. nov., a parasite of the gall bladder of *Distichodus engycephalus* Günther, 1964 (Distichodontidae) form spindle-shaped and elongated spores, that measure 15.2 (14.0-16.2) µm long × 6.0 (5.0-6.7) µm broad; its polar capsules are quite unequal and respectively measure 6.0 (5.0-6.5) × 3.3 (3.0-3.6) µm for the larger and 4.7 (4.0-5.6) × 3.0 (2.3-3.3) µm for the smaller. *Myxobolus magai* sp. nov., a gill parasite of *Labeo batesii* Boulenger, 1911 (Cyprinidae) form ovoid spores with the anterior end larger with small protuberance, that measure 10.6 (9.0-12.0) × 6.3 (5.5-7.0) µm. Its polar capsules measure 2.8 (2.4-3.4) × 2.3 (2.0-3.0) µm.

Keywords  Myxozoa; *Myxidium tetraodoni* sp. nov.; *Myxidium anisocapsularis* sp. nov.; *Myxobolus magai* sp. nov.; Parasite; Freshwater fish; Cameroon

Introduction

Due to the increasing needs for animal protein production worldwide, fish industry is a major activity in human populations today [1]. However, fishes are vulnerable to various parasitic infections, including Myxosporidiosis. Myxosporidia can infect numerous fish organs and cause a wide variety of damages [2]. The extent of damage to host tissues and organs depend on the parasite species, its life cycle, infection intensity, and host response [3]. Many pathogenic species can be responsible of severe epizootics in fish farms and hatcheries. Indeed, in natural and artificial environments, Myxosporidia can cause the loss of production and death of fishes. Some parasitized fishes are unsightly and considered unfit for human consumption. Human health can be affected by Myxosporidia when immunodepressed people are contaminated with infected fish [4].

Knowledge of fish parasites is a prerequisite for a rapid diagnosis of the pathogen responsible for epizootic diseases. Early diagnosis can lead to preventive measures that remain the best way to reduce epidemics [5]. Thus it is necessary to record and report new parasites and pathological conditions when they are discovered because such information may be useful in the future as a baseline data for assessing the ecosystems health in the face of global warming [6]. Based on the morphological and metric characteristics of the spores, the number of Myxosporidia described around the world is estimated at 2200 species belonging to 64 genera and 17 families [7].

Eiras et al. [8,9] provided a synopsis of 905 species of *Myxobolus* Bütschli [10]; this genus has the largest global distribution and the high number of Myxosporidia species. With more than 232 species, the genus *Myxidium* Bütschli [10] is numerically the second genus of Myxosporidia [11]. Species of the genus *Myxidium* are predominantly coelozoic (rarely histozoic) infecting the gall bladder, the urinary bladder and the urinary tubules of the kidneys [2,12,13]. The number of Myxosporidia parasites of African freshwater fish is estimated at about 270 species [14,15]. Those of the freshwater fishes in Cameroon are represented by about 80 species, with forty of them belonging to the genus *Myxobolus* and nine to the genus *Myxidium* [14,16,17]. Taxonomic studies and description of new species of Myxosporidia throughout the world suggested that the diversity of species in this group of parasites is largely underestimated.

During a study of Myxosporidia parasites of teleosts of great importance of food and economic in Cameroon, we found three new species whose complete descriptions are given in the present paper. These species are: *Myxidium tetraodoni* sp. nov. a parasite of *Tetraodon lineatus* Linnaeus, 1758 (Tetraodontidae), *Myxidium anisocapsularis* sp. nov. found in *Distichodus engycephalus* Günther, 1964 (Distichodontidae) and *Myxobolus magai* sp. nov. a gill parasite of *Labeo batesii* Boulenger, 1911 (Cyprinidae).
Figure 1: Microphotograph (optical microscopy) of a Trophozoite of Myxidium tetraodoni sp. nov. with a granular endoplasm, the spores are formed in pairs within a pansporoblast. Scale bar: 5 μm.

Figure 2: Microphotograph (optical microscopy) of fresh spore of Myxidium tetraodoni sp. nov. : polar capsules are spherical. Scale bar: 5 μm.

Figure 3: Microphotograph (optical microscopy) of spores of Myxidium tetraodoni sp. nov. stained with May-Grünwald-Giemsa. Scale bar: 5 μm.

Figure 4: Microphotograph (optical microscopy) of fresh spore of Myxidium anisocapsularis sp. nov. : polar capsules are unequal. Scale bar: 5 μm.

Material and Methods

Fish examined were sampled in the Maga detention lake from March to May 2016. Maga is a small village of the Mayo-Danay Division (situated between latitude 10° and 13° North and longitude 14° and 16° East), in the Far North Region of Cameroon. The Maga reservoir lake is located at 77 km from the city of Maroua and covers an area of 39000 hectares. The climate in this locality is the Sahel-Sudanian type, which is characterized by a long dry season from October to April and a short rainy season from May to September. The average temperature is 28°C [18]. Maga is located in a floodplain and its vegetation consists of the shrub savannah (weakly wooded) and the herbaceous steppe with grass. Its soil, predominantly clay-sandy, take a clayey-silty shade around the lake [18].

Fish were captured using gill nets. In the field, once the fish were caught, a buttonhole was made on the ventral surface of each host individual. The latter were immediately immersed in a 10% formalin solution contained in a plastic container, before being brought to the laboratory. Systematic position of sampled fishes was taken from Lévêque et al. [19,20]. The species captured are: *Tetraodon lineatus* (Tetraodontidae), *Distichodus engycephalus* (Distichodontidae) and *Labeo batesii* (Cyprinidae).

Results

*Myxidium tetraodoni* sp. nov.

**Vegetative form:** Circular and polysporous plasmodia are found in the urinary bladder of the host. Ectoplasm is clear and smooth. In the granular endoplasm, spores are formed in pairs within pansporoblasts (Figure 1).

**Spores:** Of small size (11.6 μm length on average), spores are ellipsoidal with a bulging middle part and rounded ends (Figures 2-11). Shell valves striated, one can count 9 to 12 fine striations on each (Figure 11). Polar capsules are spherical and equal (Figures 3 and 11). Within each of them, 4 to 5 coils of polar filament can be found (Figure 10). A granular sporoplasm is located between polar capsules.

**Measurements of the spore:** (Table 1).

**Host:** *Tetraodon lineatus* Linnaeus, 1758 (Tetraodontidae).
**Location:** Maga (in the reservoir lake) in Cameroon (Central Africa).

**Location in the host:** Urinary bladder

**Prevalence:** 76.9% (20 individuals fish parasitized out of 26 examined).

*Remarks:* Averages of the parameters measured are followed by minimal and maximal values in brackets.

LS: length of the spore; WS: width of the spore; PC: relative length of the polar capsules (=: equal); LPC: length of the polar capsules; WPC: width of the polar capsules; FC: number of polar filament coils; StV: Number of striations on shell valves;– absent or not reported in the species description; ±: shell valves striations are present, but the number was not reported in the species description.

**Table 1:** Comparative description of *Myxidium tetraodoni* sp. nov. with morphologically similar species (measurements in micrometre).

**Myxidium anisocapsularis** sp. nov.

**Vegetative form:** Not observed; spores, sometimes abundant, were found free in the bile (Figure 12).

**Spores:** Of medium size (15.2 μm long on average), they are spindle-shaped, elongated (2.5 times longer than wide), with a turgid medial part and acuminate extremities (Figures 4 and 5). Each valve carries 8 to 11 longitudinal striations (Figures 5 and 13). The suture line is straight. The polar capsules are piriiform and quite unequal (Figures 6 and 13). The larger polar capsule contains 5 to 6 loops of the filament and the smaller 4 to 5 (Figure 12). A finely granular sporoplasm is located in the extra-capsular space.

**Measurements of the spore:** (Table 2).

**Host:** *Distichodus engycephalus* Günther, 1964 (*Distichodontidae*).

**Location:** Maga (in the reservoir lake) in Cameroon (Central Africa).

**Location in the host:** Gall bladder.

**Prevalence:** 15.38% (04 parasitized fish out of 26 examined).

Averages of the parameters measured are followed by minimal and maximal values in brackets.

LS: length of the spore; WS: width of the spore; PC: relative length of the polar capsules (=: equal; #: unequal); LPC: length of the polar capsules; WPC: width of the polar capsules; FC: number of polar filament coils; StV: Number of striations on shell valves; =: absent or not reported in the species description; ±: shell valves striations are present, but the number was not reported in the species description;

*:Referring to the largest polar capsule;

**:Referring to the smallest polar capsule.

**Myxobolus magai** sp. nov.

Vegetative form: This Myxosporidia forms whitish and ovoid cysts, located between the secondary gill lamellae. These plasmodia are polysporous and measure 172–300 × 116 μm-200 μm. one can find 10 to 132 cysts per individual fish host (Figures 2-11).

Spores: of small size (10.6 μm long on average), mature spores are ovoid with the anterior end larger and hillocky, the posterior end being wider part of the spore is occupied the 1/3 of the wider length of polar capsules. Polar capsules are observed at the mid length of the polar capsules. Pola Capsules are ovoid and symmetrical (Figures 7 and 8). They occupy the 1/3 of the spore cavity, converge and open at the anterior end of the spore (Figure 8). Each of them contains 4 to 5 coils of polar filament (Figure 14). The iodinophilous vacuole is found in a developped sporoplasm (Figures 7 and 15).

**Measurements of the spore:** (Table 3).

**Host:** *Labeo batesii* Boulenger, 1911 (Cyprinidae).

**Location:** Maga (in the reservoir) in Cameroon (Central Africa).

**Location in the host:** gills.

**Prevalence:** 28.5% (04 parasitized fish out of 14 examined).
**Myxobolus sarigi** Oreochromis aureus x O. niloticus Spleen Israel 11.3 –13.1 (9.9 –9.6) = 4.5 (4.1– 5.2) 3.2 (2.9– 4.0) 4–5 A Landsberg [30]

Average of the parameters measured are followed by minimal and maximal values in brackets.

Table 3: Comparative description of *Myxobolus magai* sp. nov. with morphologically similar species (measurements in micrometre).

**Discussion**

*Myxidium tetraodoni* sp. nov.

By the spore shape, this myxosporidia come close to some species previously described in Africa and other continents. *Myxidium brienomyri* Fomena et al. [22], develops large trophozoites in the gall bladder of *Brienomyrus brachyistus* (Mormyridae) in Cameroon. Spores of this species are longer (13.7 μm on average) and less wide (6.47 μm on average); although spherical, the polar capsules are more developed (4.2 μm diameter on average).

*Myxidium nyongensis* Fomena et al. [22], develop circular and large trophozoites in the gall bladder of *Barbus jae*, *B. aspilus*, *B. guirali* and *B. martorelli* (Cyprinidae) in Cameroon. Its spores are ellipsoidal with rounded ends but longer (12.38 μm on average) and less wide (6.47 μm on average) compared to those of the species in description.

*Myxidium latesi* Kostoïngué, Faye et al. [23] (host: *Lates niloticus* in Chad) are oval, with pointed ends. They are considerably more developed (15.44 μm long × 8.33 μm wide) compared to those of the present species.

*Myxidium macrocapsulare* Auerbach [24] (host: *Scardinius erythrophthalmus* in Europe and *Grunnian Aplodinotus* in America) forms free spores in the gall bladder with slightly curved ends pointed in the opposite directions. These spores are narrower (5.3 μm-6.8 μm) with polar capsules rather ovoid (4.6 μm × 3.8 μm on average).

The spores of *Myxidium latesi* Kostoïngué, Faye et al. [23] (host: *Lates niloticus* in Chad) are oval, with pointed ends. They are considerably more developed (15.44 μm long × 8.33 μm wide) compared to those of the present species.

*Myxidium macrocheili* Mitchell [26] (host: *Catostomus macrocheilus* in North America) have comparable length with those of our parasite (11.7 μm on average); however, they are less wide (6.6 μm on average) with ovoid polar capsules which measure 4 × 3.5 μm on average.

The parasite of *Tetraodon lineatus*, which differ from other species by numerous characteristics, is probably new. We propose the name *Myxidium tetraodoni* sp. nov. referring to the generic name of the fish host. This is the first time a Myxosporidia is described in *Tetraodon lineatus*. 

![Figure 12: Line drawing of a spore of Myxidium anisocapsularis sp. nov. : the spore is fusiform with unequal polar capsules.](image-url)
Myxidium anisocapsularis sp. nov.

The only Myxidium species so far described in African Distichodontidae is Myxidium distichodi Kostoïngué, [23], a parasite of the gall bladder of Distichodus engycephalus in Chad. The spores dimensions of M. distichodi (16.3 (16-17) μm × 6.5 (6-7) μm) are comparable to those of the species being described but their polar capsules are equal (constant character).

The general form of spores of the species in description recalls that of Myxidium parachannae Sakiti [27], parasite of the gall bladder of Parachanna obscura in Benin. However, the spores of M. parachannae are much longer (21 μm-25 μm) and less wider (3 μm-5 μm).

Myxidium birgii Fomena et al. [22], found in the gall bladder of Aphydrosemion bivittatum (Cyprinodontidae) in Cameroon form fusiform spores, with striated valves and a bulging medial part, but longer (17.7 μm-22.5 μm long). The spores shape of Myxidium mendehi Fomena et al. [28], recalls that of the species we are describing; however, this parasite of the kidneys of Barbus guirali and B. martorelli (Cyprinidae) form smaller spores (9.9 μm × 4.1 μm in average).

The spores of Myxidium camerounensis Fomena et al. [22], although fusiform with a bulging medial part, are longer (22.04 μm on average), with equal polar capsules containing 7 to 9 loops of polar filament.

The spores of Myxidium petrocephali Fomena et al. [22] (host: Petrocephalus simus in Cameroon) are slightly arched, more developed (24.14 μm × 8.05 μm on average) with symmetrical and larger polar capsules (10.3 μm × 4.3 μm on average).

Myxidium aydai Abdel-Baki [29], parasite of Caesio suevicus in Egypt produces spores measuring 23 μm long on average with symmetrical polar capsules measuring 7.2 μm on average.

Out of all Myxosporidian species of the genus Myxidium described so far in the world, no one form spores with unequal polar capsules. We believe that the parasite of Distichodus engycephalus is new and propose the name Myxidium anisocapsularis sp. nov., refering to the asymmetry observed on its polar capsules.

Myxobolus magai sp. nov.

By the spore’s general shape, the present parasite resemble some species of Myxosporidia previously described. Myxobolus galilaeus Landsberg [30], forms diffuse spores in melano-macrophage centers of the kidneys and spleen of Sarotherodon galilaeus in Israel. These spores are ovoid with the anterior end flattened. They are larger (11.9 μm × 9.1 μm on average) and 3 to 12 folds are found on the suture line. Myxobolus sarigi Landsberg [30], a systemic parasite of Cichilidae in Israel, forms spores with the anterior end wider. These spores are wider (8.4 μm on average) with larger polar capsules (4.5 μm × 3.2 μm on average).

Myxobolus cichlidarum Abakar-ousman [31], parasitizes fins, gills, eyes, spleen, kidneys and liver of Oreochromis niloticus and...
Sarotherodon galilaeus in Chad. Although ovoid with a wider anterior end, the spores of this species, differ from those of our species by the following characteristics: larger size (15 μm × 9.6 μm on average), more developed polar capsules (5.8 μm × 3.2 μm on average), presence of an intercapsular appendix.

The spores of Myxobolus eirasi Kaur et al. [32] (parasite of Cirrhina mirgala in India), are morphologically comparable to those of our parasite, but shorter (8.4 μm-8.8 μm) with smaller polar capsules (1.4 μm-1.75 μm).

Fall et al. [33] described Myxobolus gandiolensis in the kidneys of Tilapia guineensis in Senegal. This Myxosporidium differs from the species in description by its wider spores (10.3 (9-12) μm) and its spherical polar capsules.

In India, Myxobolus yogendrai (Triparthi, 1952) Landsberg et al. [34], parasite Cirrhina mirgala; its spore, although ovoid with a wider anterior end, possess an intercapsular triangle and four valvular folds.

Myxobolus nossenensis Fomena et al. [35], is a parasite of the spleen and kidneys of Sarotherodon galilaeus and Tilapia mariae (Cichlidae) in the Noun River in Cameroon. Sproes of this species are more developed (14.3 μm × 12.8 μm on average), same as its polar capsules (5.8 μm × 4.5 μm on average) and a well-developed intercapsular appendix is present.

These differences lead to think that the parasite of Labeo batesii is a new species. We propose the name Myxobolus magai sp. nov., referring to the locality of Maga where the fish host were captured.

Conclusion

Although Africa has one of the most diverse ichthyological fauna, and the genus Myxidium is the second major group of Myxosporidia, the description of Myxidium tetraodoni sp. nov. and M. anisocapsularis sp. nov. Only brings up to 18 the number of species of the genus Myxidium described in freshwater fishes of this continent, and to 11 the number of species of the genus described in freshwater fishes of Cameroon. M. tetraodoni is the first Myxosporidium described in fishes of the family Tetraodontidae and M. anisocapsularis is the only species of the genus Myxidium hitherto found with unequal polar capsules. Species of the genus Myxidium are generally coelozoic and parasites in freshwater.

Compliance with Ethical Standards

Animals used followed a protocol approved and authorized by Institutional Animal Care and Use Committee at Animals Biology and Physiology Department, Faculty of Science, University of Yaounde I, Cameroon.
