Abstract

Effects of n-butanol fraction of *Gongronema latifolium* leave extract on some liver function and histological parameters in CCl₄-induced oxidative damage in Wistar albino rats were assessed. Fifty-four (54) Wistar albino rats were divided into treatment group and LD₅₀ groups. Group A (normal control) was given feed and water, Group B (vehicle control) was injected with olive oil intraperitoneally, while the rest groups (C, D, E, F and G) were injected intraperitoneally with a single dose of CCl₄ (148 mg/kg) as a 1:1 (v/v) solution in olive oil and all the animals were fasted for 36 hours. This was repeated once every week for a period of four (4) weeks. At the end of 28 days of treatment, liver marker enzymes studies showed that there was significant (p<0.05) increase in the serum activities of ALT, AST, ALP and bilirubin in CCl₄-induced control group when compared with the normal control and induced treated groups but there was no significant (p>0.05) difference of these liver marker enzymes and bilirubin levels between the normal control and induced treated groups. Antioxidant assay on the liver homogenate showed that there was significant (p<0.05) decrease in SOD, CAT, GPx and a significant increase (p<0.05) in MDA of CCl₄-induced control rats when compared to the normal control rats but there was no significant (p>0.05) difference between the normal control and induced treated groups. These findings suggested that n-butanol fraction of methanolic leave extract of *G. latifolium* may have anti-hepatotoxic and antioxidative effects against CCl₄-induced liver damage in rats.

Keywords: *Gongronema latifolium*; Antioxidant; n-butanol; CCl₄; Histology

Introduction

*Gongronema latifolium* (Asclepiadaceae), is a perennial climber forest leafy vegetable with woody hollow glabrous stems below and characterized by greenish yellow flowers [1]. It is widespread in tropical Africa such as Senegal, Chad and DR Congo as well as grows in the forest of south eastern and western Nigeria where it is widely used for medicinal and nutritional purposes [2]. *G. latifolium* occurs in rainforest, deciduous and secondary forests, and also in mangrove and disturbed roadside forest, from sea-level up to 900 m altitude. In Nigeria, information available from the indigenous traditional healers claimed that a decoction of the chopped [3] leaves of *G. latifolium* has been used in the production of several herbal products which are taken orally [1] for the treatment of stomach upsets and pains, dysentery, malaria, typhoid fever, worm and cough [4]. Asthma patients chew fresh leaves to relieve wheezing [1] and a decoction of the roots, combined with other plant species, is taken to treat sickle cell anaemia. A maceration of the leaves in alcohol is taken to treat bilharzia, viral hepatitis and as a general antimicrobial agent [5]. It is also taken as a tonic to treat loss of appetite [4]. Previous studies have revealed that other plants with polyphenols exhibit clear anti-hepatotoxic properties [1], and that flavonoids could protect the liver against oxidative injury induced by CCl₄ in vivo [4]. Although many other plants have been reported to possess anti-hepatotoxic properties, the scientific authentication of most of them such as *G. latifolium* which is used traditionally to treat several diseases is unavailable [3]. The qualitative phytochemical screening of the methanolic leave extract of *G. latifolium* revealed the presence of glycosides, alkaloids, saponin, flavonoids, tannins, and the absence of free anthraquinone. The quantitative analysis of phytochemical constituents of *G. latifolium* leaves is presented in Table 1. The crude extract showed high tannin content followed by glycosides, alkaloids and saponin. The results in Table 2 also showed that the n-butanol fraction has higher flavonoids, polyphenols and ascorbic acid content than the ethylacetate fraction. The aim of this work is to provide some scientific support for the health benefit of *G. latifolium*. To achieve this, studies were carried out to investigate the phytochemical constituents of *G. latifolium* and to evaluate the anti-hepatotoxic activities of n-butanol fraction of methanolic leave extract of *G. latifolium* against oxidative damage induced by CCl₄ in Wistar albino rats.

Materials and Methods

Chemicals/reagents

All assays kits were from Randox Laboratories Ltd. Ardmore, Co. Antrim UK. Chemicals and reagents used were purchased from Sigma Chemical Company St. Louis U.S.A. and chemicals used were of analytical grade. Folin ciocăline phenol reagent, gallic acid, carbon tetrachloride (Sigma-Aldrich), distilled water, normal saline.

Plant material and extraction

Fresh leaves (blend) of *G. latifolium* were obtained from a...
Quantitative analysis of phytochemicals

Determination of saponins was carried out according to the gravimetric method of AOAC, 1984 [10].

Determination of total flavonoids was done using the method of Boham and Kocipal-Abyazan [11].

Determination of tannin was done using the standard method described by AOAC [12].

Determination of Glycosides was done using the standard method described by AOAC [10].

Determination of total phenolic contents (TPC) using the Folin-Ciocalteu method adopted by Amin et al. [13] was used.

Ascorbic Acid Contents was determined using the method described by Barros et al. [14].

Determination of Alkaloids was carried out using the procedure described by Harbone (1973) with slight modification by Edeoga et al. [15].

Animals

A total of 54 apparently healthy Wistar albino rats of both sexes weighing between 100-150 g were obtained from the animal house, Department of Pharmacology, Ahmadu Bello University, Zaria, Kaduna State and were allowed to acclimatize to the laboratory environment for a period of two weeks before the commencement of the experiment. They were fed daily with grower mash from Vital Feeds Company and water ad libitum during the stabilization period.

Acute toxicity study

The median lethal dose (LD₅₀) of n-butanol fraction was conducted in order to select a suitable dose for the evaluation of the effects of n-butanol fraction. This was done using the method described by Lorke (1983) [16]. In the initial phase, rats were divided into 3 groups of 3 rats each and were treated with 10 mg, 100 mg and 1000 mg of n-butanol fraction per kg body weight orally. They were observed for 24 hours for signs of toxicity, including death. In the final phase, 3 rats were divided into 3 groups of one rat each, and were treated with n-butanol fraction based on the findings in the first phase. The LD₅₀ was calculated from the results of the final phase as the square root of the product of the lowest lethal dose and the highest non-lethal dose, i.e., the geometric mean of the consecutive doses with 0 and 100% survival rates were recorded.

Animal grouping

A total of 54 Wistar albino rats were used. The rats were divided into carbon tetrachloride induced liver damage group of 6 rats each and LD₅₀ group.

Carbon tetrachloride induced group

Group A: Normal control Rats were given feed and water only. This served as the normal control group (NC).
Group B: Rats were treated with olive oil and served as vehicle control group (VC).

Group C: Rats were treated with 148 mg/kg b.wt. carbon tetrachloride (CCl₄) in olive oil. This serves as the CCl₄-induced liver damage group (IC).

Group D: Rats were treated with 148 mg/kg b.wt. CCl₄ in olive oil+100 mg/kg b.wt. Silymarin as standard drug (CCl₄+Std).

Group E: Rats were treated with 148 mg/kg b.wt. CCl₄ in olive oil + n-butanol fraction (CCl₄+BF).

Group F: Rats were treated with 148 mg/kg b.wt. CCl₄ in olive oil + n-butanol fraction (CCl₄+BF).

Group G: Rats were treated with 148 mg/kg b.wt. CCl₄ in olive oil + 200 mg/kg b.wt. n-butanol fraction (CCl₄+BF).

**Induction of liver damage**

The liver damage was induced by the administration of carbon tetrachloride (CCl₄). Rats were injected intraperitoneally with a single dose of CCl₄ (148 mg/kg body weight) as a 1:1 (v/v) solution in olive oil and were fasted for 36 hours before the administration of n- butanol fraction [17]. This was done once a week for a period of four weeks. The administration of n- butanol fraction was done daily by oral intubation for the period of 28 days.

**Collection and preparation of sera samples**

At the end of 28 days of treatment, the animals were sacrificed by decapitation using chloroform anaesthesia and blood samples were collected from the head wound in plain bottles (for biochemical parameters). The Blood samples collected in plain tubes were allowed to clot and the serum separated by centrifugation using Labofuge 300 centrifuge (Heraeus) at 3000 rpm for 10 minutes and the supernatant (serum) collected was subjected to biochemical screening.

**Collection of liver**

Immediately after the blood was collected, the liver was quickly excised, trimmed of connective tissues, rinsed with saline to eliminate blood contamination, dried by blotting with filter paper and weighed (so as to calculate the relative weight) and kept on ice. Certain gram of the liver was crushed in 50 mM potassium phosphate buffer (pH 7.4) using mortar and pestle (homogenization) while the rest of the organs were made into permanent slides and examined under high (X250) resolution microscope with photographic facility and photomicrographs were taken.

**Statistical analysis**

The data were analyzed by the analysis of variance (ANOVA) using SPSS program (version 17.0 SPSS Inc., Chicago, IL, USA). The differences between the various animal groups were compared using the Duncan Multiple Range Test. The results were expressed as mean ± standard error of mean (SEM). P value less than 0.05 was considered as significant (P<0.05).

**Results**

The Percentage Yield of Methanolic Leave Extract and Fractions of *G. latifolium*

The percentage yield (w/w) of the crude extract is (10.24%) and the various fractions have aqueous residue as the highest yield (45.80%), followed by n-butanol fraction (25.14%), ethylacetate fraction (10.70%) and n-hexane fraction has the lowest yield (6.66%).
Lethal Dosage (LD₅₀) determination for n-butanol fraction of *G. latifolium*

No death was recorded after the oral administration up to a dose of 5000 mg/kg b.wt.

**Effects of n-butanol fraction of *G. latifolium* on Packed Cell Volume**

The effect of sub-chronic oral administration of n-butanol fraction of *G. latifolium* methanolic leaves extract and silymarin (Standard drug) at 100 mg/kg b.wt, 150 mg/kg b.wt and 200 mg/kg b.wt. on packed cell volume in CCl₄-induced liver damage in albino rats for 28 days is shown in Figure 1. The result showed that the packed cell volume (PCV) level of induced control group was significantly (P<0.05) lowered than the PCV level of normal control group, but there was no significant (P>0.05) difference between the PCV level of the normal control animals and all the induced treated animals.

**Effects of n-Butanol fraction of *G. latifolium* on body and organ weight change**

Changes in body weight of rats induced liver damage treated with n-butanol fraction of *G. latifolium* methanolic leaves extract and silymarin (Standard drug) for a period of 28 days is represented in Figure 2. The results showed no significant (P>0.05) difference in the body weight change of all the induced treated groups compared with the normal control group. However, the CCl₄ induced liver damage control group shows a significant (P<0.05) decrease in body weight compared with the induced treated and normal control groups.

Changes in organ weight of rats induced liver damage treated with n-butanol fraction of *G. latifolium* methanolic leaves extract and silymarin (Standard drug) for a period of 28 days is represented in Table 3. The result showed that there was no significant (P>0.05) difference between the percentage change in liver weights of the entire induced treated group compared with the normal control rats. However, the induced control rats presents a significant (P<0.05) higher percentage change in liver weights compared with the normal control rats.

**Biochemical studies**

**Assessment of liver function indices:** Liver function indices of alanine aminotransferases (ALT), aspartate amino transferases (AST), alkaline phosphatases (ALP), total protein (TP), albumin (ALB) and bilirubin (DB and IB) concentrations in the serum of CCl₄-induced liver and kidney damage rats after the daily oral administration of n-butanol fraction of *G. latifolium* and silymarin for 28 days is represented in Tables 4 and 5. There was significant (P<0.05) increase in activities of all these liver marker enzymes (ALT, AST and ALP) in the CCl₄-induced liver damage control group when compared with the normal control. The activities of ALT, AST and ALP in the induced treated groups were however significantly (P<0.05) reduced when compared with induced not treated group. The n-butanol fraction and silymarin significantly (P<0.05) increase the serum total protein levels of the induced treated groups compared with the induced not treated group but there was no significant (P>0.05) difference between the serum total protein levels of all the induced treated groups and the normal control group. Also serum albumin concentrations of the induced not treated group was significantly (P<0.05) lower than the normal control and the induced treated groups, but there was no significant (P>0.05) difference between the serum albumin levels of all the induced treated groups and the normal control group. Also, the levels of bilirubin in the induced treated groups were however significantly (P<0.05) reduced when compared with induced not treated group, but there was no significant (P>0.05) difference between the bilirubin levels of all the induced treated groups and the normal control group.

**In vivo antioxidant studies**

**Effects of n-butanol fraction of *G. latifolium* on some endogenous antioxidant enzymes in the liver of CCl₄-induced liver damage albino rats:** The effects of daily oral administration of n-butanol fraction of *G. latifolium* and Silymarin for 28 days on the level of malondialdehyde (MDA) and some endogenous antioxidant enzymes (catalase, glutathione peroxidase and superoxide dismutase) of the liver of CCl₄-induced liver damage rats is represented in Table 6. There was...
a significant ($P<0.05$) increase in the level of malondialdehyde (MDA) and a significant ($P<0.05$) decrease in the level of catalase (CAT), glutathione peroxidase (GPx) and superoxide dismutase (SOD) of the CCl$_4$ induced liver damage control rats compared with the normal control. There was no significant ($P>0.05$) difference in the levels of MDA and endogenous antioxidant enzymes of all the induced treated groups when compared with the normal control group.

**Histopathological studies**

Effects of n-butanol fraction of *G. latifolium* on liver: The histological section of the liver of CCl$_4$-induced oxidative damage rats treated with n-butanol fraction of *G. latifolium* methanolic leave extract and silymarin for 28 days is shown in Plate 1. The histopathological examinations of liver section of normal control group showed normal cellular architecture with distinct hepatic cells. CCl$_4$-induced control group liver showed an intense hepatic necrosis with vascular congestion, vacoulation, lymphocyte hyperplasia and degeneration of normal hepatic cells. The induced treated groups showed almost normalization of the hepatic cells. On daily oral administration of n-butanol fraction of *G. latifolium* methanolic leave extract and silymarin brought the liver back to moderate hepatic necrosis.

**Discussion**

The preliminary phytochemical studies revealed the presence of glycosides, saponins, tannins, alkaloids, and flavonoids in the crude methanolic leave extracts of *G. latifolium*. The presence of these groups when compared with the normal control group.

phytochemicals in the plant, accounts for its usefulness as medicinal plant [27]. The quantitative phytochemical analysis showed that tannins had the highest concentration in the crude extract (Table 1) whereas the n-butanol fraction had the highest concentration of flavonoids, ascorbic acid and polyphenols [28,29] when compared to the ethylacetate fraction (Table 2). Plant phenolics, flavonoids and ascorbic acid scavenging potentials and metal chelating ability is [33] dependent upon their unique structure, the number and position of the hydroxyl groups [34-36]. The potential health benefits associated with these phytochemicals has generated great interest among scientists for the development of natural in vitro antioxidant compounds from plants [37,38].

Haematological investigation provides information on the general pathophysiology of the blood and reticuloendothelial system [39,40]. Fairbarks [41] showed that xenobiotics causes low PCV level which may be associated with the oxidation of sulphhydryl groups of the erythrocyte membrane thus, inflicting injury to the erythrocytes membrane. This is in agreement with the present study as packed cells volume (PCV) values in rats exposed to CCl4 gave low levels of PCV. The n-butanol fraction approached the normal control (Figure 1). This finding suggests that the administration of the n-butanol fraction of the methanolic leave extract of G. latifolium to patient with remarkable low PCV level may be attributed to the inability of the hepatocytes to take up bilirubin, impaired conjugation of bilirubin and reduced hepatocyte uptake of bilirubin, impaired conjugation of bilirubin and reduced hepatocyte secretion of bilirubin [48,49]. However, since there are significant elevation of direct (conjugated) and indirect (unconjugated) bilirubin levels in the blood serum of CCl4-induced not treated group compared to the normal control when CCl4 level as a result of liver necrosis or may be due to inability of the liver to conjugate bilirubin in the case of elevated indirect bilirubin which can be attributed to the inability of the necrotic liver to conjugate bilirubin or the inability of the hepatocytes to take up bilirubin [50-52]. Also, elevated bilirubin may also be due to obstruction in the flow of bile within the liver or in the bile duct as a result of severe liver damage [43].

There was significant (P<0.05) restoration of these liver marker enzymes activities as well as bilirubin and serum proteins levels on administration of the n-butanol fraction and silymarin for 28 days at a dose of 100 mg/kg b.wt., 150 mg/kg b.wt. and 200 mg/kg b.wt. The reversal of these serum liver marker enzymes in CCl4-induced treated groups towards a near normalcy by the n-butanol fraction approached the normal control (Figure 1). This finding suggests that the administration of the n-butanol fraction of the methanolic leave extract of G. latifolium to patient with remarkable low PCV level may increase their packed cell volume. It implies that the n-butanol fraction may possess constituents that would trigger the production of more blood cells [42,43].

Changes in the body weight after CCl4 dosing have been used as a valuable index of CCl4-related organ damage by [44,45] and thus, will be applicable in this study in order to justify the effects of CCl4 on the body and organ weights of these animals. The decrease in changes in body weight (Figure 2) and consequent increase in liver weights seen in CCl4-induced treated group was considered to be as a result of direct toxicity of CCl4 and/or indirect toxicity that lead to liver damage (Table 3). This indicates that CCl4 may have induced hypertrophy of the cells of these organs as well as elicited remarkable tissue damage [46] which may have led to the observed effects on the body and organ weights of these animals. However, all the induced treated groups experienced a significant increase in body weight changes as well as reduced change in organ weights, suggesting the possible curative effects of the n-butanol fraction of G. latifolium against liver injury after CCl4 induction.

Assessment of liver can be made by estimating the activities of serum ALT, AST and ALP which are enzymes originally present at higher concentration in cytoplasm [47]. When there is hepatothropy, these enzymes leak into the blood stream in conformity with the extent of liver damage [48,49]. Administration of CCl4 caused a significant (P<0.05) elevation of these liver marker enzyme levels and a consequent decrease in the level of serum proteins when compared to normal control group (Tables 4 and 5). The elevated level of these marker enzymes with a corresponding decrease in serum proteins level observed in the CCl4-induced not treated group corresponded to the extensive liver damage induced by CCl4 which may lead to an impaired protein turnover. These results are in agreement with previous finding that the activity levels of serum ALT, ALP and AST were significantly elevated as well as a significant decrease in serum protein levels in rats after CCl4 administration [50-53].

Also, the significant (P<0.05) elevation of bilirubin levels in the CCl4-induced not treated group when compared to the normal control and the induced treated groups may be as a result of haemolytic anaemia that may be associated with oxidative damage to red blood cells thus, leading to elevated bilirubin level since bilirubin is an intermediate product in haemoglobin breakdown in the liver [47]. Again, this elevated bilirubin level may also be associated with reduced hepatocyte uptake of bilirubin, impaired conjugation of bilirubin and reduced hepatocyte secretion of bilirubin [48,49]. However, since there are significant elevation of direct (conjugated) and indirect (unconjugated) bilirubin levels in the blood serum of CCl4-induced not treated group, this may be attributed to the inability of the hepatocyte to secrete conjugated bilirubin as envisioned in elevated direct bilirubin level as a result of liver necrosis or may be due to inability of the liver to conjugate bilirubin in the case of elevated indirect bilirubin which can be attributed to the inability of the necrotic liver to conjugate bilirubin or the inability of the hepatocytes to take up bilirubin [50-52]. Also, elevated bilirubin may also be due to obstruction in the flow of bile within the liver or in the bile duct as a result of severe liver damage [43].

Values are Means ± SEM. Values with different superscript down the columns are significantly different (P<0.05).

NC: Normal Control rat, VC: Vehicle control rats, CCl4: Carbon tetrachloride, IC: CCl4 Induced liver damage control rats, CCl4 + BF: CCl4 Induced liver damage rats+100mg/kg b.wt. of n-butanol fraction, CCl4 + BF: CCl4 Induced liver damage rats+150mg/kg b.wt. of n-butanol fraction, CCl4 + BF: CCl4 Induced liver damage rats+200mg/kg b.wt. of n-butanol fraction, CCl4 + Std: CCl4 Induced liver damage rats+100mg/kg b.wt. of Standard Drug (Silymarin).

MDA: Malondialdehyde, SOD: Superoxide dismutase, CAT: Catalase, GPx: Glutathione peroxidase.
bilirubin and serum proteins returns to normalcy with the healing of hepatic parenchyma cells as well as the regeneration of hepatocytes [14]. It is therefore, a clear manifestation of the hepatocurative effects of the n-butanol fraction of G. latifolium. Following the administration of the n-butanol fraction of G. latifolium and silymarin, the hepatocytes showed close to normal cellular architecture which may be as a result of regeneration and repair of liver cells [43,53].

Antioxidant activity or scavenging activity of the generated free radicals is important in the curative effect of CCl₄-induced hepatotoxicity. The body has an effective defence mechanism to prevent and neutralize free radicals-induced damage. This is accomplished by a set of endogenous antioxidant enzymes such as superoxide dismutase, glutathione peroxidase and catalase. Decrease in enzyme activity of superoxide dismutase (SOD) is a sensitive index in hepaticcellular damage and is the most sensitive enzymatic index in liver injury [55,56]. The increased level of malondialdehyde (MDA) in the liver tissue of the rats administered CCl₄ (Table 6) may be as a result of the enhanced membrane lipid peroxidation by free radicals generated and failure of antioxidant defence mechanisms to prevent formation of excessive free radicals [50,57,58]. Also, the decreased activity of SOD, GPx and CAT in the liver tissues of CCl₄-induced rats may be due to high concentration of these free radicals generated by CCl₄ which may lead to decreased level or inactivation of these endogenous antioxidant enzymes [59]. Treatment with n-butanol fraction of G. latifolium significantly (P<0.05) increased the levels of SOD, GPx and CAT activities and a consequent significant (P<0.05) reduction in MDA. The effects of the n-butanol fraction were comparable to the standard drug (Silymarin). Thus, this result suggests that n-butanol fraction of G. latifolium contains free radical scavenging activity due to the presence of in vitro antioxidants, which could exert beneficial action against pathophysiological alterations caused by the presence of superoxide and hydroxide free radicals as well as hydrogen peroxide indicating the regeneration of damaged liver cells [2,53].

The histopathological studies of the liver in the CCl₄-induced control group showed that CCl₄ caused an intense vascular congestion, vacuolation, lymphocyte hyperplasia and necrosis (Plate 1) indicating its hepatotoxicity. This result is in agreement with [60]. Following the administration of the n-butanol fraction of G. latifolium and silymarin, the hepatocytes showed close to normal cellular architecture which may be as a result of regeneration and repair of liver cells [43,53]. In line with these findings, it’s obvious that histopathological examinations are in agreement with observed biochemical analysis. This result is in agreement with the report [2,53,61-68].

Conclusions

The result of this study has scientifically justified the traditional use of G. latifolium in the management of human diseases. The result showed that the n-butanol fraction of methanolic leave extract of G. latifolium possess in vitro antioxidants which may have contributed to its significant anti-hepatotoxic properties. The histological examination showed that the n-butanol fraction of G. latifolium has curative effect on the liver in CCl₄-induced liver damage rats. The n-butanol fraction of G. latifolium is comparable to the standard drug (silymarin). This work provides the phytotherapeutic potential of n-butanol fraction of G. latifolium that may be useful to scientists and researchers in the nutraceutical industry.

Recommendations

1. There is need to carry out a bioactivity-guided fractionation, isolation and identification of the bioactive constituents of the n-butanol fraction which is responsible for the observed pharmacological activities.

2. There is need to carry out chronic toxicity studies of the n-butanol fraction of the plant so as to ascertain the safety of long term usage on animals.
