Resveratrol Nanoemulsion: A Promising Protector Against Ethinylestradiol-Induced Hepatic Cholestasis in Female Rats

Hussein MA*, Kasser AK, Mohamed AT, Eraqy TH and Asaad A

Medical Laboratory Department, Faculty of Applied Medical Science, October 6 University, Egypt

ABSTRACT

Ethinylestradiol (EE) induced cholestasis was reported in female rats-model. The present article aimed to investigate anticholestatic activity of Resveratrol Nanoemulsion (RENE) against EE-induced cholestasis in adult female rats. The mean particle size of RENE was 49.5 ± 0.05 nm and zeta potential of +15.75 with the observed shapes of nanoparticle was spherical. Also, the median lethal dose (LD50) of RENE in rats was 795 mg/kg body weight. Administration of 1/20 LD50 RENE (39.75 mg/kg.b.w) to EE-treated rats normalize serum cholesterol level as well as against an increase of serum TBA, bilirubin concentration. The treatment also resulted in a significant increase in hepatic SOD and GPx. RENE inhibited serum ALP, ALT and γ-GT activities, as well as reduced serum TNF-α, NO, MMP-2 MMP-9 and hepatic MDA as compared to EE-treated rats. The results clearly suggest that RENE has a powerful prophylactic action in cholestasis induced by EE.

INTRODUCTION

Cholestasis is characterized by oxidative stress, inflammation and disorders of the liver, bile duct and pancreas [1]. When bile flow is stopped, the pigment bilirubin, a waste product that’s formed when old or damaged red blood cells are broken down, escapes into the bloodstream and accumulates [2]. The presence of a lesion in the cellular parenchyma is common in a large number of chronic liver diseases, such as viral hepatitis, alcoholic hepatitis, and cholestasis [3]. Intrahepatic cholestasis evaluated in susceptible women during pregnancy after administration of estrogens [4]. EE is widely used to cause experimental cholestasis in rat’s model [5]. EE down-regulated of Na+-taurocholate co transporter polypeptide (Ntcp) expression leading to decrease sinusoidal uptake of bile acids [6,7]. In addition, γ-GT levels were raised after the administration of EE in the prophylactic treatment. As, earlier mentioned, γ-GT and ALP are employed to detect impaired bile flow (cholestasis) [8-11]. Among the many drugs for liver injury, resveratrol is the most clinically popular for patients and is known to have hepatotherapeutic and anti-fibrotic properties [5]. Resveratrol has also been proven effective in several research fields, such as protecting against genomic injury, increasing hepatocyte protein synthesis, decreasing the activity of tumor promoters and stabilizing mast cells. Pharmaceutical and medicinal activity of red wine depends on its several factors including the grape variety, vineyard location, cultivation system, climate and soil type and production process among others [12,13]. In addition to its free radical scavenging properties, silymarin increases antioxidant enzymes, such as SOD and catalase and inhibits lipid peroxidation [14,15]. According to many authors however, it has a low bioavailability [16]. Nanotechnology is at the forefront of cancer research. This, technology allows scientists to target cancer cells [17]. Nanoparticles can decrease side effects in patients by directly targeting the area of disease and eliminating the need to circulate through the body [18,19]. When encapsulating drugs into nanoparticles, researchers observed improved drug solubility, controlled drug release, enhanced bioavailability, increased stability and improved long-term storage (versus non-encapsulated drugs) [20]. These attributes are promising and could be the traits needed to combat disease. Not surprisingly, a phenolic compounds such as resveratrol, an excellent scavenger...

of reactive oxygen species and anticholetstatic activity [21-22]. The aim of this study was to investigate in vivo, the anticholetstatic and hepatoprotective activities of resveratrol nanoemulsion against EE-induced cholestasis in female rats.

MATERIALS AND METHODS

Materials

RPMI1640 (Roswell park memorial institute) medium with L-glutamine (Cambrex, Belgium), Resveratrol, Trypan Blue, Bovine serum albumin, Glutaraldehyde 50% (Sigma, USA). RES, EE and Tween 80 were obtained from Sigma Chemical Co. (St. Louis, MO, USA). All other chemicals used in this study were of the analytical grade.

Resveratrol nano-emulsion preparation

100 mg Bovine Serum Albumin (BSA) is dissolved in 12 ml distilled water; dissolve the resveratrol 24 mg in 24 ml ethanol then add drop wise the ethanolic solution on the BSA solution under stirring (500 rpm); then add 3 ml 11% glutaraldehyde and leave on stirring overnight [23].

Resveratrol nano-emulsion characterization

The crystalline nature and grain size of Resveratrol Nanoemulsion (RENE) was carried out by X-ray Diffraction (XRD) pattern at 25-28°C with a D8 Advance X-ray diffractometer (Bruker – Germany) with a nickel (Ni) filtered using CuKα (λ=1.54184 A0) radiations as an X-ray source. Infrared Spectrum (IR) of sample is registered using Nicolet 6700 (Thermo scientific–USA). The thermal analysis was measured using Thermo Gravimetric Analysis (TGA) TGA -50 (Shimadzu, Japan) Morphology and size of RENE were examined by Scanning Electron Microscope (SEM, JSM- 690, JEOL, Inc., Tokyo, Japan) and Field Emission Transmission Electron Microscopy (FETEM, JSM- 2100F, JEOL Inc.) at an accelerating voltage of 15Kv and 200 Kv.

Animals used

The animals used in the study, Female albino rats weighing around 150-170 g (96 rats; 60 for LD50 estimation and 36 for anti-cholestasis activity) were obtained from the animal house of National Cancer Institute Animal House, Egypt. They were housed in groups of 6 around 150-170 g (96 rats; 60 for LD50 estimation and 36 for anti-cholestasis activity) were obtained from the animal house of National Cancer Institute Animal House, Egypt. They were housed in groups of 6

Determination of LD50 of resveratrol nanoemulsion

Resveratrol nanoemulsion was orally administrated in different doses to find out the range of doses which cause zero and 100% mortality of animals. A range doses was determined for each extract. LD50 was determined by administration of resveratrol nanoemulsion in different doses 350, 500, 700, 900, 1100 and 1300 mg/kg orally, in six groups, 10 animals in each. After administration of the tested resveratrol nanoemulsion, animals were observed individually every hour during the first day and every day for 21 days. Behavior and clinical symptoms of animals were noted throughout the duration of the experiment. The LD50 was calculated by Finney, method using following formula [24]:

LD50 = Dm - [Σ(Z×d)] / n

Dm= The largest that kill all animals.
Σ= The sum of (z × d).
Z= Mean of dead animals between 2 successive groups.
d= The constant factor between 2 respectively doses.
n= Number of female rats in each group.

Measurement of lipid peroxidation

SOD and GPx were determined in liver tissues by red formazan
dye reduction produced and coupled reaction method with GR respectively [35-36]. Also, thiobarbituric acid reactive substances assay kit to measure the liver lipid peroxidation products, MDA equivalents [37].

Histological assessment

Portions of the tissue from liver were used for histopathological examination. Tissues were fixed in 10% buffered formalin (pH 7.2) and dehydrated through a series of ethanol solutions,embedded in paraffin and routinely processed for histological analysis according to the method of Bancroft and Steven [38]. Sections of 2 µm thickness were cut and stained with haematoxylin-eosin for examination. The stained tissues were observed through an Olympus microscope (BX-51) and photographed by a Charge-Couple Device (CCD) camera.

Statistical analysis

Data were presented as mean ± SEM. The presence of significant differences among means of groups was determined by one-way ANOVA using SPSS/18 Software for Windows (USA). P values of <0.05 and 0.01 were considered to indicate statistical significance.

Results

Results showed that the IR spectrum infrared spectrogram of the resveratrol raw powder shows a phenol hydroxyl group absorption peak at 3252 cm⁻¹ and benzene ring absorption peaks at 2827, 2920 exists. Infrared spectrogram of resveratrol nanoemulsion shows a hydroxyl group absorption peak at 3436 cm⁻¹ exists. Light scattering techniques as well as Transmission Electron Microscopy were used to evaluate size, zeta potential and morphology of the nanoformulations. As shown in Figure 1 resveratrol nanoemulsion had size of around 49.5 ± 0.05 nm with negative zeta potential of +15.75. From the equation the LD₅₀ of resveratrol nanoemulsion was calculated to be 795 mg/kg b.w. (Table 2). A single oral dose of resveratrol nanostructure showed increase in heart rate, rapid respiration within 1 to 2 hours at dose levels used (350, 500, 700, 900, 1100 and 1300 mg/kg). The LD₅₀ (rat, oral) is therefore estimated to be beyond 795 mg/kg body weight. The temperature of the animals’ extremities dropped with the toes and tail being cool. Biochemical profiles of the treated animals are presented in Tables 3 and 4. The oral administration of RENE (39.75 mg/kg b.w.) did not cause any significant changes in ALT, ALP, total bilirubin, TBA, γ-GT, TNF-α, NO and cholesterol levels when compared to distilled water and tween 80 control groups. The levels of serum ALT, ALP, total bilirubin, TBA, γ-GT, TNF-α and NO of EE-treated animals were significantly increased. However, there was a significant decrease (p<0.05) of the serum total cholesterol when compared to distilled water and tween 80 control groups. Pre- and post-treatment of animals with RENE significantly reduced ALT, ALP, total bilirubin, TBA, γ-GT, TNF-α and NO levels as well as significantly increased cholesterol (P<0.01), as compared with the EE group. The cholestatic effect of EE was controlled in the rats treated with RENE as demonstrated by the restoration the hepatocytes biomarkers. Also, MMP-2 and -9 are both implicated in the EE-treated rats as compared with the normal control group (P<0.01). Not surprisingly, there were dramatic elevations of the liver MDA and plasma levels of both MMPs as well as deletion of liver SOD and GPx activities in the EE-treated. RENE pre- and post-treatment at RENE significantly (P<0.01) enhanced liver MDA, SOD and GPx as well as plasma MMP-2 and -9 levels as compared to the EE-treated group (Tables 5 and 6).

\[ LD₅₀ = 1300 - \left[ \frac{5025}{10} \right] = 795 \text{ mg/kg b.w.} \]
Histopathology examination

Gallbladders sections from the distilled water, tween 80 and RENE treated groups had normal appearance and histology (Figure 2a-c). Generally, there were no observable changes in architecture of livers and kidneys of treated animals compared to the control. The histology was consistent with the normal levels of ALT, AST, bilirubin, oxidative stress biomarkers and inflammatory mediators.

**Table 3**: Effect of Resveratr...
The liver is a multipurpose organ in the body involved in the regulation of internal chemical environment. Therefore damage to the liver inflicted by a hepatotoxic agent is of critical consequence [5]. The changes are associated with EE-induced liver toxicity are comparable to that of hepatic cholestasis [39,40]. This is due to the infiltration of fatty acids and glycerols into the hepatocytes upon damage to cell membranes [41-43]. Also, the increase in bile flow due to cholesterol precipitation may be responsible for the reduced level of bile acids in serum after EE administration [43]. In agreement with results obtained in similar investigations by Hussein the treatment with EE in the present study elicited a significant decrease in the levels of serum cholesterol as well as increase in the levels of serum, bile acids, ALT, ALP, \( \delta \) GT, and BA, total bilirubin, and MDA levels [5]. This was evident in both prophylactic and curative studies. Treatment with the RENE (39.75 mg/kg.b.w.) however significantly increased in the levels of serum cholesterol as well as decrease in the levels of serum, bile acids, ALT, ALP, \( \delta \) GT, and BA, total bilirubin, and MDA levels which were elevated by EE-treatment. Total serum bilirubin can also be employed to detect cholestasis in addition to the GGT and ALP and also as a measure of hepatocellular damage [44,45]. In the curative study, total bilirubin levels in the serum of the rats increased significantly in the EE-treated group. This increase was reduced almost to normalcy upon damage to cell membranes [41-43]. Also, the increase in bile flow due to cholesterol precipitation may be responsible for the reduced level of bile acids in serum after EE administration [43]. In agreement with results obtained in similar investigations by Hussein the treatment with EE in the present study elicited a significant decrease in the levels of serum cholesterol as well as increase in the levels of serum, bile acids, ALT, ALP, \( \delta \) GT, and BA, total bilirubin, and MDA levels [5]. This was evident in both prophylactic and curative studies. Treatment with the RENE (39.75 mg/kg.b.w.) however significantly increased in the levels of serum cholesterol as well as decrease in the levels of serum, bile acids, ALT, ALP, \( \delta \) GT, and BA, total bilirubin, and MDA levels which were elevated by EE-treatment. Total serum bilirubin can also be employed to detect cholestasis in addition to the GGT and ALP and also as a measure of hepatocellular damage [44,45]. In the curative study, total bilirubin levels in the serum of the rats increased significantly in the EE-treated group. This increase was reduced almost to normalcy when treated with the (39.75 mg/kg.b.w.) of RENE. The results of the study suggest that RENE is both proactive and responsive in protecting against EE-induced hepatotoxicity. It is however more bioactive when given to treat an existing damage to the liver. Five days dosing with EE, TNF-\( \alpha \) and NO accumulate in serum, detectable as inflammatory mediators, and there is continued produce of free radicals in the endoplasmic reticulum [46,47]. Deregression of the system can perpetuate inflammatory processes that lead to tissue damage and organ dysfunction [48]. As expected, liver sections from untreated EE-injured rats had higher degree of inflammation and steatosis than the treated groups. Rats that received 100 \( \mu \)g/kg, EE, showed significant cellular degeneration, necrosis and inflammation. Although both TNF-\( \alpha \) and NO are commonly thought of as inflammatory mediators because of their high concentrations in liver inflammation and specific for liver lipid peroxidation [49]. The effect with the RENE Pre-and post-treatment was similar in the RENE-treated groups. Higher phase II enzyme activity is expected to be released in rats fed with RENE; mainly SOD and GPx. The possibility of TNF-\( \alpha \) and NO to generate ROS during metabolism has been postulated [50]. The ability of RENE to attenuate the hepatoxic effect of EE could be due to the antioxidant property of RENE may have since EE is known to exert its toxicity through the induction of free radicals [51]. Polyphenols for example are known to be soluble chain breaking inhibitors of the peroxidation process, acting as scavengers of intermediate peroxy and alkoyl radicals and chelating metal ions [52]. Prevention of DNA oxidation is also achieved by these polyphenols mainly by quenching free radicals and modulating biometabolism enzymes [5]. Our results indicated that MMP-2 and -9, both involved in rats exposed to EE (100 \( \mu \)g/kg b.w.), were greatly up-regulated in the serum as well as liver of rats with cholestasis. It has been previously shown that reduced maternal MMP-2 levels in the serum is linked to fetal inflammation and preterm labor [5], while increased MMP-2 serum levels are commonly observed in peripartum cardiomyopathy [53]. Furthermore, changes in synthesis of MMP-2 and -9 were associated with pre-eclampsia [54,55]. It was also reported that during defective placentation, the secretions of MMP-2 and -9 were markedly suppressed, causing intrauterine growth restriction 38. Moreover, the abnormal increase in levels of MMP-2 and -9 on the amnion of fetal membrane was shown to contribute to premature membrane rupture 39 during pregnancy, levels of MMP-2 and -9 in the serum are tightly regulated, perturbations of which often leads to various maternal and fetal disorders. In the present study, MMP-2 and -9 were found to be up-regulated, suggesting that both MMPs are indeed involved in EE-treated rats, which necessitates further investigations into their functions in the disease. Besides intrahepatic cholestasis of pregnancy, cholestasis is reportedly the major syndrome of hepatotoxicity, in particular those induced by ingestion of harmful herbal products [56,57]. MMPs are also thought to contribute to hepatotoxicity, supported by reports demonstrating the protective effects against hepatotoxicity exerted.
through down-regulation of MMP-9 [58]. On a related note, RENE (39.75 mg/kg b.w.) has been shown to inhibit MMP-9 activity by several independent reports. For instance, resveratrol was shown to inhibit MMP-9 expression in both breast cancer cells and rheumatoid fibroblast-like synoviocytes to suppress their migration and invasion [59]. Given these accumulating evidences supporting the effect of RENE to inhibit MMPs, we aimed to examine whether RENE functioned in a similar fashion in our rat EE-induced ICP model, to suppress both MMPs and thereby ameliorate ICP symptoms. Indeed, treatment with RENN significantly down-regulated MMP-2 and -9 in the liver as well as in the serum of the ICP rats. It is worth noting that MMP-2 and -9 may be reduced at both mRNA and protein levels by RENN treatment, suggesting that the suppression of MMPs by RENE could occur as early as the transcriptional stage. Future investigations are needed to reveal the mechanisms underlying the inhibitory effects of RENE on MMP-2 and MMP-9, as well as to identify potential targets of RENE other than these two MMPs. The histology of the livers showed no signs of toxicity in the I, II control groups of rats. Also, it could be seen that RENN did not show any observable toxicity to the gallbladder compared to the control. From the histopathological observations, it could be seen that EE at the dose of (100 µg/kg) caused severe fatty changes in the livers of rats. In the present study, the histological findings prove that RES affected the recovery of the liver structure in rats with EE-induced liver cirrhosis. Indeed, there was remarkable reduction in fibrosis extent and a decrease of stellate infiltration in rats treated with RENN (39.75 kg.b.w.) groups compared to the control EE group. In addition, the most novel and relevant finding was that RENN supplementation was accompanied by the alleviation of bile duct proliferation and ductular reaction in this model. RENN was also able to reduce newly formed bile ducts (Figure 2). Since the proliferation of bile ducts is an early event in cholestasis-related changes, the attenuation of hepatic injury and fibrosis in rats by RES might be associated with alleviation of ductular reaction. Propylactic effect of RENN against EE-induced cholestasis has not been reported earlier to my knowledge, and this study is perhaps the first observation of its kind.

CONCLUSION

In summary, we established a rat model of intrahepatic cholestasis induced by ethinylestradiol, with symptoms highly resembling those observed clinically in women with ethinylestradiol. Next, using this rat model, the present study showed that levels of cholestatic indices, oxidative stress biomarkers, MMP-2 and -9 were markedly up-regulated in intrahepatic cholestatic rats. Furthermore, the present results showed that the symptoms in the cholestatic rats with EE were significantly ameliorated by RENN. Altogether, our findings in the present study showed that RENN has powerful anticholestatic activity against EE-induced cholestasis, in addition to its antioxidant action and free radical-scavenging activities. Nevertheless, to translate the effects of RENN from animal models to clinical settings, further investigations are required to confirm the efficacy as well as safety of RENN.
